

Problem Set 2

Due 6pm Friday September 23

Reading: Sec 22.1 and 22.2 of Big Bang Cosmology from Review of Particle Physics.

Note two differences in conventions: (1) we use dimensionless a and they use dimensional R for the scale factor; (2) our cosmological constant Λ is included in the energy density ρ in the Friedmann equation while they write it out as a separate term in their (22.8).

1. The Fate of Three Universes

Depending on the average energy density, a universe can be open, flat, or closed. Consider three universes with $\Omega_0 = 0.3, 1.0$, and 3.0 , respectively. Assume $H_0 = 70 \text{ km s}^{-1} \text{ Mpc}^{-1}$ and a matter-dominated universe (i.e. ignore radiation and any dark energy component).

- Express H_0 in units of inverse years. (Show your work.)
- For the closed universe, calculate the time (in years) when the expansion reaches a maximum, and the time when the “Big Crunch” occurs.
- For the flat universe, compute \dot{a} in the limit as $t \rightarrow \infty$.
- For the open universe, use the parametric expression derived in lecture to compute \dot{a} in the limit as $t \rightarrow \infty$. Compare your answer to part (c).
- Using the fact that $a(t_0) = 1$, compute t_0 for all three models.
- On a single plot, draw three curves for the scale factor a vs. proper time t for the three universes. Use linear scales for both axes.

Line up the $a(t)$ curves so that $t_0 = 0$ for **all three models** (i.e. we are shifting the time axis for each model so that all three universes have $a = 1$ at $t = 0$ instead of $a = 0$ at $t = 0$). Your time axis should go from -20 Gyr to +50 Gyr.

Be sure to label the time when the Big Bang occurs on each curve (this will occur in the past at negative t), and the times when the closed universe reaches a maximum and undergoes the Big Crunch.

2. The Robertson-Walker Metric

An alternative form of the Robertson-Walker metric is given by

$$ds^2 = c^2 dt^2 - a^2(t) \left[d\chi^2 + S_k^2(\chi)(d\theta^2 + \sin^2 \theta d\phi^2) \right], \quad (1)$$

where χ is a new radial coordinate, and k is the curvature constant.

- Find the function $S_k(\chi)$ for each of the three cases of k : $k = 0$, $k > 0$, and $k < 0$.
- Using this metric, derive an expression for the ratio of circumference to radius for a circle for each of the three cases of k .

- (c) When the radial coordinate χ is small compared with the radius of curvature $|k|^{-1/2}$, what value does the ratio in (b) approach for $k > 0$? What about $k < 0$?
- (d) For $\chi = 0.5 |k|^{-1/2}$, compare the ratio in (b) for a negatively curved space with that of a flat space. Repeat it for a positively curved space.
- (e) For $\chi = 15 |k|^{-1/2}$, compare the ratio in (b) for a negatively curved space with that of a flat space. Comment on any trend you have learned from (c), (d) and (e).
